Initial Model Training Code, Model Validation and Evaluation Report

The initial model training code for toxic comment classification on social media will be shared through a future screenshot, showcasing the process of text preprocessing, vectorization, and training logistic regression models. The model validation and evaluation report will summarize the performance of multiple models, including their accuracy, precision, recall, F1 score, and AUC-ROC metrics, with the details presented via respective screenshots.

Initial Model Training Code (5 marks):

Paste the screenshot of the model training code

```
[ ] #clean the comment_text in both the datasets
train_df['comment_text'] = train_df['comment_text'].map(lambda com : clean_text(com))
test_df['comment_text'] = test_df['comment_text'].map(lambda com : clean_text(com))

[ ] #define all_text from entire train & test data for use in tokenization by vectorization
#Fixed: Use train_test instead of train_text
train_test = train_df['comment_text'] # This line was correct
test_train = test_df['comment_text'] # This line was correct
all_text = pd.concat([train_test, test_train]) # Changed train_text to train_test and test_text to test_train

▶ #vectorize the data
#import and instantiate CountVectorizer
from sklearn.feature_extraction.text import CountVectorizer
word_vect = CountVectorizer(
    strip_accents='unicode',
    analyzer='word',
    token_pattern=r'\w{1,}',
    stop_words='english',
    ngram_range=(1, 1)
)
```

```
# learn the vocabulary in the training data, then use it to create a document-term matrix
word_vect.fit(all_text)

CountVectorizer
CountVectorizer(stop_words='english', strip_accents='unicode',
                token_pattern='\\w{1,}')
```

+ Code + Text

```
[ ] from sklearn.model_selection import train_test_split

# Assuming 'all_text' is your complete dataset of text documents
train_text, test_text = train_test_split(all_text, test_size=0.2, random_state=42)

[ ] #transform the data using the earlier fitted vocabulary, into a document-term matrix
train_features = word_vect.transform(train_text)
test_features = word_vect.transform(test_text)
```

Model Validation and Evaluation Report (5 marks):

| Model | Summary | Training and Validation Performance Metrics |
|---------|---|--|
| Model 1 | <p>Logistic Regression is highly interpretable, computationally efficient, and provides a solid baseline for toxic comment classification tasks. However, it faces challenges with high-dimensional data (leading to overfitting), imbalanced datasets (toxic comments are often less frequent), and a lack of contextual understanding. Enhancing its performance involves using word embeddings like Word2Vec or GloVe, feature engineering, and hyperparameter tuning.</p> | <pre>> from sklearn.linear_model import LogisticRegression from sklearn.metrics import accuracy_score logreg=LogisticRegression(C=16.0) [23] ✓ 0.0s > submission_binary=pd.read_csv('submission_binary.xls') [15] ✓ 0.2s print(test_df.columns) [17] ✓ 0.0s ... Index(['id', 'comment_text', 'toxic', 'severe_toxic', 'obscene', 'threat', 'insult', 'identity_hate'], dtype='object')</pre> |

The process begins with data preprocessing, including text cleaning (removing special characters, URLs, HTML tags, and stopwords), tokenization (splitting text into words or tokens), and vectorization (converting text to numerical format using techniques like Bag of Words or TF-IDF). Logistic Regression is trained using these features, employing the sigmoid function to predict probabilities. The model calculates the probability of a comment being toxic and learns the weights for each feature using optimization techniques like Gradient Descent. A comment is classified as toxic if the predicted probability exceeds a set threshold (e.g., 0.5), and the threshold can be adjusted for improved recall or precision.

```

mapper = {}
for label in cols_target:
    mapper[label] = logreg
    filename = str(label + '_model.sav')
    print(filename)
    print('... processing {}'.format(label))
    y = test_df[label]
    mapper[label].fit(test_features.y)
    pickle.dump(mapper[label], open(filename, 'wb'))
    y_pred_x = mapper[label].predict(test_features)
    print('Training accuracy is {}'.format(format(accuracy_score(y, y_pred_x))))
    test_y_prob = mapper[label].predict_proba(train_features)[0,1]
    submission_binary[label] = test_y_prob

```

Logistic Regression is a simple and effective algorithm used for binary or multi-class classification tasks, including toxic comment classification on social media. Toxic comment classification involves identifying comments that are abusive, hateful, or harmful, and can be a binary classification task (toxic vs. non-toxic) or multilabel classification (e.g., hate speech, offensive language, or spam).

The process begins with data preprocessing, including text cleaning (removing special characters, URLs, HTML tags, and stopwords), tokenization (splitting text into words or tokens), and vectorization (converting text to numerical format using techniques like Bag of Words or TF-IDF). Logistic Regression is trained using these features, employing the sigmoid function to predict probabilities. The model calculates the probability of a comment being toxic and learns the weights for each feature
